Ref: Development of iPSC-derived neural progenitors secreting GDNF for the treatment of ALS.

App Number: DISC2 - 16686

Dear CIRM Board,

We are very excited to have submitted a DISC2 proposal that describes a new iPSC derived neural progenitor product engineered to release the powerful growth factor GDNF to prevent motor neurons from dying in ALS. We are doing this now to ensure a continual pathway of cell product development following our very successful safety studies (completed or currently underway) using a very similar product but derived from a single unique source of fetal brain tissue. iPSCs will provide a similar cell product but completely renewable and much easier to commercialize.

We were the only grant to be to have a minority report as we had more than 35% of the committee recommend this grant for funding (6 were YES and 8 were NO). The major issue seemed to have been lack of novelty. We agree this product is similar to our last one – but very importantly it allows us to produce a renewable product that is expandable to treat thousands of patients and will have much more global impact if our early studies are successful.

We hope that there will be enough funding for this round to include this proposal that aims to deliver a unique combined cell and gene therapy product to patients with ALS.

A handwritten signature in black ink, appearing to read 'CNS' followed by a stylized flourish.
